Hi Saad,

Thank you for applying for the position Backend Django Engineer.
Congratulations on successfully passing our initial screening!

As the next step in our hiring process, we kindly ask you to complete the following coding assessment:

Assignment:

- Build an API that takes inputs of start and finish location both within the USA
- Return a map of the route along with optimal location to fuel up along the route -- optimal mostly means cost effective based on fuel prices
- Assume the vehicle has a maximum range of 500 miles so multiple fuel ups might need to be displayed on the route
- Also return the total money spent on fuel assuming the vehicle achieves 10 miles per gallon
- Use the attached file below for a list of fuel prices
- Find a free API yourself for the map and routing

Requirements:

- Build the app in latest stable Django
- Send your results for this project within 3 days of receiving the exercise
- The API should return results quickly, the quicker the better
- The API shouldn't need to call the free map/routing API you found too much. One call to the map/route API is ideal, two or three is acceptable
- Make a Loom where you use Postman or similar API platform to demonstrate the API working while also giving a quick overview of your code (5 minutes max)
- Share the Github code with us

After completing, please attach the Github code and a Loom video in the question in this message.
